

Correlation and Anti-correlation of East Asian Summer and Winter Monsoons during the Last 21,000 Years

Xinyu Wen

Dept. of Atmospheric & Oceanic Sciences, School of Physics, Peking University, Beijing, China

Introduction

Understanding the past significant changes of the East Asia Summer Monsoon (EASM) and Winter Monsoon (EAWM) is critical for improving the projections of future climate over the East Asia. One key issue that has remained outstanding from the paleo-climatic records is if the evolution of the EASM and EAWM are anti-correlated. Here we show that the EASM and EAWM are positively correlated on the orbital timescale in response to the precessional forcing, but are anti-correlated on millennial timescales in response to North Atlantic melting water forcing by using a set of long-term transient simulations of the climate evolution of the last 21,000 years. The relation between EASM and EAWM can differ dramatically for different time scales because of the different response mechanisms, highlighting the complex dynamics of the East Asian monsoon system and the challenges for future projection.

Model & Numerical Experiments

Model: NCAR CCSM3 and isotope-enabled version of CAM3 (called "isoCAM3", After Noone, 2010)
Simulation Length: 22,000 years (22ka to present) for Experiment 1 and 2; 50 years for each snapshot in Experiment 3
Experiment 1: All-forcing transient run (TRACE21) with forcing of ORB + CO₂ + MWF + ICE
Experiment 2: 4 transient runs with single-forcing of ORB / CO₂ / MWF / ICE separately
Experiment 3: 23 snapshot (slice) runs using isoCAM3 with prescribed SST/SICE derived from TRACE21

Forcing Details:
ORB: Solar insolation with 22ka-through-present realistic orbital parameters
CO₂: Greenhouse gases (CO₂, CH₄, and N₂O) concentrations from ice cores
MWF: North Atlantic and Antarctica surrounding melting water flux
ICE: Land ice sheets from ICE-5G dataset
Others: Modifications of coastlines due to sea level changes

Results from All-forcing Run: Two Key Modes

Results from Single-forcing Runs

Conclusions

The evolution of EASM and EAWM is correlated at the orbital scale in response to the precessional forcing, but anti-correlated at millennial time scale in response to the meltwater forcing and the resulting AMOC change. The monsoon correlation is also slightly affected by the rising GHGs and retreating ice sheets.

The new understanding from a modeling framework reconciled the conflicting interpretations on the co-variability between EASM and EAWM in proxy records, and demonstrated that their relationship is influenced by multiple physical processes on diverse timescales. This work presents great challenge and potential to understand the response of the East Asian monsoon system to global climate changes in the past and future.
